

Resistance and Rewilding: The Return of Beavers to Knapdale Forest

Rosamund Portus

Summary

This story follows the work of the “Scottish Beaver Trial,” a five-year project that sought to restore beaver populations in Scotland. The trial began in 2009, when three families of beavers were released in Knapdale Forest in the hope that they would make it their new home. After a challenging start the beavers managed to thrive in their new environments, transforming the landscape and increasing biodiversity. Two years after the trial concluded, the beavers were awarded “native species” status, ensuring their continued protection. The trial demonstrates the potential of rewilding projects to offer hope in an era of environmental instability.

All over the world, species are dying at an unprecedented rate. As such, it has become generally agreed within the realm of natural sciences that we are already living through or, at the very least, hurtling towards the sixth mass extinction: an era characterized by the extensive loss of life on Earth. Consequently, it is also a time in which stories of sorrow and grief have come to dominate the narratives surrounding humans' relationships with nonhuman others. A direct response to the loss of species in this time of increasing extinction is the practice of rewilding. Rewilding seeks to restore species in their original locations, in the hope of reinvigorating both the species and the habitats in which they live. However, contemporary rewilding projects are not seeking to return environments to their historic states. Rather, as Monbiot (2013) explains, through the reintroduction of species to an area, rewilding seeks to allow the natural environmental processes of that area to resume, unhindered and uncontrolled by humans. One such example of rewilding is that of the "Scottish Beaver Trial" project, a five-year venture that sought to successfully reintroduce beavers into Knapdale Forest, Mid-Argyll. The project started in 2009 and was led by the Scottish Wildlife Trust, in partnership with the Royal Zoological Society of Scotland and the Forestry Commission Scotland.

Although there has been discussion about reintroducing beavers since the 1990s, and even one failed application for a trial made in 2002, the Scottish Beaver Trial first became reality in May 2008, when the Scottish Government finally approved an application for a trial reintroduction. This was the first legally supported case of mammal reintroduction in the UK, and its success was paramount in gaining support for future rewilding projects. Exploring the history of beavers in Scotland, Conroy and Kitchener (1997) write that beavers were first thought to have become extinct in this location during the fifteenth and sixteenth centuries and, somewhat

typically, it is thought to have been the result of exploitative human behaviours, such as over-hunting and habitat destruction. The reintroduction trial began on 28 and 29 May 2009, when 11 Eurasian beavers, originally captured in Norway, were released into three separate freshwater lochs in Knapdale Forest. Jones and Campbell-Palmer (2014) revealed in the Scottish Beaver Trial's final report that, in the following days, it was estimated that over ten million people either read, heard, or listened to news of the beavers' release. This creature's charismatic qualities, coupled with the experimental and somewhat controversial nature of the trial, meant that the project attracted unprecedented interest.

The trial lasted five years and, despite expected hiccups and a challenging start, was an overall success. In 2010 the first beaver kit was born, and today the Scottish beaver populations remain relatively stable. In 2016, two years after the conclusion of the trial, the beavers were granted "native species" status by the Scottish government, ensuring their continued protection.

The beavers' new status was partly awarded due to their reputation as ecosystem engineers: they tend to modify their environments by creating dams, canals, wetlands, and lodges that attract the attention of species that might not normally reside in those environments. As such, during the trial the beavers significantly increased biodiversity by transforming the landscape of Knapdale Forest and increasing habitat heterogeneity, as is shown in figures 2 and 3. Although the modifications that the beavers made to their new habitats stirred some controversy, particularly amongst local farming populations, the impact of the beavers' alterations to their environments was predominantly positive. Another aspect that fed into the success of this project was the extent to which those working on the project used the trial to engage with external individuals and communities, through benefiting local economies, offering new educational experiences, and generally making their research

accessible to others. The development of an active, professional [website](#) that offered both scientific and video updates, educational resources, and visitor information demonstrates the thoroughly inclusive nature of the trial. Following the overall success of the Scottish Beaver Trial, beavers have now also been reintroduced in areas such as Devon and Cornwall.

In a time in which both popular and academic texts are filled with stories of loss and destruction, it is vital that narratives such as this, of positive environmental action and outcomes, continue to be produced. My intention in telling this story of a successful rewilding project is not to bypass the controversial nature of many rewilding projects or to produce a rosy picture of how humans might respond to or resist the extinction of species. Rather, it is intended as a positive reminder that there are ways in which the efforts of a few individuals can work to save or revive many of the species and habitats that have become fundamental to the existence of humans and, indeed, all species. Rewilding projects, if approached with considerable caution and implemented properly, can provide an avenue of hope and offer a way of resisting the ever-increasing losses that are occurring in the modern world.

About the author:

Rosamund Portus

Rosamund Portus is a Doctoral Researcher based at the University of York. She is part of the WRoCAH funded [Extinction Network](#), specialising in the study of bees, extinction and environmental change. Much of her work focuses around humans' relationships with non-humans during the Anthropocene. Rosamund's other research interests concern the connections between children and nature in the contemporary world.
