The Quality of Web-Based Osteoarthritis Information on the Internet: A Cross-Sectional Study

Background:

Osteoarthritis (OA) is a long-term condition that affects over 8.75 million people in the United Kingdom (UK). Approximately 43% of people in the UK search for health and medical information online. However, health information on the internet is of variable quality. Research into the quality of online OA information is dated and there is a need to evaluate the existing information.

Objectives:

To assess the quality of websites which provide educational information for patients with OA.

Design: Electronic cross-sectional survey.

Methods:

The search term "Osteoarthritis" was entered into the five popular UK based search engines in order to identify 50 unique websites. Websites were then appraised by two assessors using criteria developed from available literature and recent OA NICE guidelines. The appraisal considered both general website quality and OA specific content.

Results:

Most of the websites evaluated (34/50, 68%) scored more than half of the maximum available quality score (which was 59). The median total score was 41. For general website quality, the median score was 9 (range 3-16, out of 16) and for content specific to OA, the median was 31 (range 2-43, out of 43). Websites of higher quality were created more recently, disclosed sources of information, had external seals of approval and directed the reader onto other relevant websites.

Conclusions:

The internet is a potentially useful tool for educating and empowering healthcare consumers. The websites evaluated were generally of a 'high' standard; however, there was a wide variation in the quality of information.

Keywords: Osteoarthritis, Internet, Patient education, websites

The Quality of Web-Based Osteoarthritis Information on the Internet: A Cross- 1 Sectional Study

2 Background:

3 Osteoarthritis (OA) is a long-term condition that affects over 8.75 million people in
4 the United Kingdom (UK). Approximately 43% of people in the UK search for health
5 and medical information online. However, health information on the internet is of
6 variable quality. Research into the quality of online OA information is dated and there
7 is a need to evaluate the existing information.

8 Objectives:

9 To assess the quality of websites which provide educational information for patients
10 with OA.

11 **Design:** Electronic cross-sectional survey.

12 Methods:

13 The search term "Osteoarthritis" was entered into the five popular UK based search
14 engines in order to identify 50 unique websites. Websites were then appraised by
15 two assessors using criteria developed from available literature and recent OA NICE
16 guidelines. The appraisal considered both general website quality and OA specific
17 content.

18 Results:

19 Most of the websites evaluated (34/50, 68%) scored more than half of the maximum
20 available quality score (which was 59). The median total score was 41. For general
21 website quality, the median score was 9 (range 3-16, out of 16) and for content
22 specific to OA, the median was 31 (range 2-43, out of 43). Websites of higher quality
23 were created more recently, disclosed sources of information, had external seals of
24 approval and directed the reader onto other relevant websites.

25 Conclusions:

26 The internet is a potentially useful tool for educating and empowering healthcare
27 consumers. The websites evaluated were generally of a 'high' standard; however,
28 there was a wide variation in the quality of information.

32

33 **CONTRIBUTION OF THE PAPER**

- 34 • The quality of the online OA information evaluated in this study is of a high
35 standard, however, there is a wide variability in the quality that is available.
36
- 37 • Due to the variation in the quality of online OA information, internet users may
38 find it difficult to consistently access information of a high quality.
39
- 40 • Higher quality websites tended to be created more recently, disclosed sources of
41 information, had external seals of approval and directed the reader onto other
42 relevant websites.

43

44 **Introduction**

45 Osteoarthritis (OA) is the most common form of arthritis, affecting approximately
46 15% of the population in the United Kingdom (UK) [1] and has been established as
47 one of the leading causes of pain, functional disability and impaired quality of life
48 worldwide [2]. The number of people affected by OA is expected to increase, with an
49 ageing population and an ever increasing prevalence of obesity meaning more
50 people are diagnosed with the disease every year [1]. In the UK alone over 8.75
51 million people are affected by the disease [3].

52 The range of treatments for OA varies from conventional modalities, including
53 pharmacological and surgical interventions, to non-pharmacological interventions
54 such as exercise, physical activity, education and self-management [4]. Healthcare
55 providers and people diagnosed with OA are therefore faced with several
56 management decisions. Key to facilitating a shared decision making process is
57 effective patient education. Previous studies have shown that lack of knowledge of
58 one's health can lead to depression, anxiety and poor coping strategies, while
59 effective health education can help to reduce pain and disability; highlighting its
60 importance as a vital component of self-management [5].

61 Healthcare professionals have traditionally relied upon printed sources of information
62 to help aid patient education [6]. However, since the early 2000's there has been a
63 dramatic increase in access to, and usage of the internet. In the UK alone, 38 million
64 adults use the internet everyday [7], and 43% use it as a source of health and
65 medical information [8]. Online health information can educate patients about their
66 condition, support decision making, clarify unfamiliar medical terms and identify
67 treatment options [9]. Its accessibility and convenience make it a potentially useful
68 tool for managing long term conditions such as OA, as patients are often expected to
69 manage their disease independently beyond the physical health care setting [10, 11].

70 However, the quality of internet based medical information is extremely variable [12,
71 13]. Unlike print media, there is a lack of editorial control of the internet as a
72 communication system; meaning anyone, regardless of qualification or motive can
73 place information online [4]. Issues with quality are exacerbated by the internet's
74 continued growth as a communication system; new information appears faster than it
75 can be appraised. Therefore, the greatest barrier to the internet reaching its

76 potential, as a key health related educational resource is not the quantity of
77 information, but rather finding accurate, reliable and valid information [4].

78 To assist internet users distinguish between sites that provide health information, a
79 wide range of organisations have developed methods to evaluate and assess the
80 quality of websites [14]. Organisations such as Health on the Net (HoN) [15] and the
81 DISCERN instrument [16] are some of the most commonly used forms of regulation
82 for health and medical information. In total, as many as 273 unique evaluation tools
83 have been described within the literature [18]. Yet, it is currently unclear if these tools
84 can consistently and accurately identify quality information and there remains no
85 consensus on a single best method of appraisal [14].

86 Previous research has investigated the quality of online OA information via several
87 different methods including by use of the DISCERN instrument and a self-created
88 appraisal tool [4, 6]. However, no previous research has appraised OA websites
89 against clinical guidelines for the care and management of OA [19]. Additionally,
90 previous research was carried out over a decade ago, and was not based within the
91 UK [4, 6].

92 The primary objective of this study was to assess the quality of websites that a user
93 might access in search of information about OA. The secondary objective was to
94 identify any key characteristics that indicated quality information on the internet and
95 to identify any significant correlations between these characteristics.

99 **Methods**

100 *Website Identification:*

101 A key-word search of the internet was performed in January 2015 and all websites
102 identified by February 2015. The search term "Osteoarthritis" was entered into the
103 five most popular search engines used within the UK ('Google', 'Bing', 'Yahoo', 'Ask',
104 and 'AOL') [20]. The search term was chosen as previous research has also used
105 comparatively broad search terms to duplicate the type of search a patient may
106 make [4, 21].

107 A key word search of "Osteoarthritis" at the time of the study returned between 2.6
108 million to 14.4 million results, dependent upon the search engine used. However,
109 previous studies have found that sites listed on the first search results page generate
110 92% of all traffic from an average search [22]. This indicated that individuals are
111 significantly more likely to visit websites found in the first ten matches from search
112 engines results [23]. It was therefore decided to identify 10 unique websites from
113 each of the five search engines in order to achieve a reliable sample of websites in
114 which patients would access in search of information about OA.

115 Following the initial search, a collective analysis involving all the researchers took
116 place in which the websites were subjected to exclusion criteria, consisting of three
117 phases in order to identify 50 unique websites (See Figure 1). Websites were initially
118 excluded if they were duplicates of another site that had already been identified
119 under a different search engine. Many of the search engines returned very similar
120 web results on the phrase 'Osteoarthritis'. This required the researchers to go as far
121 as the sixth page in some cases in order to obtain unique websites. When websites
122 were present in more than one of the search engine results a random programme

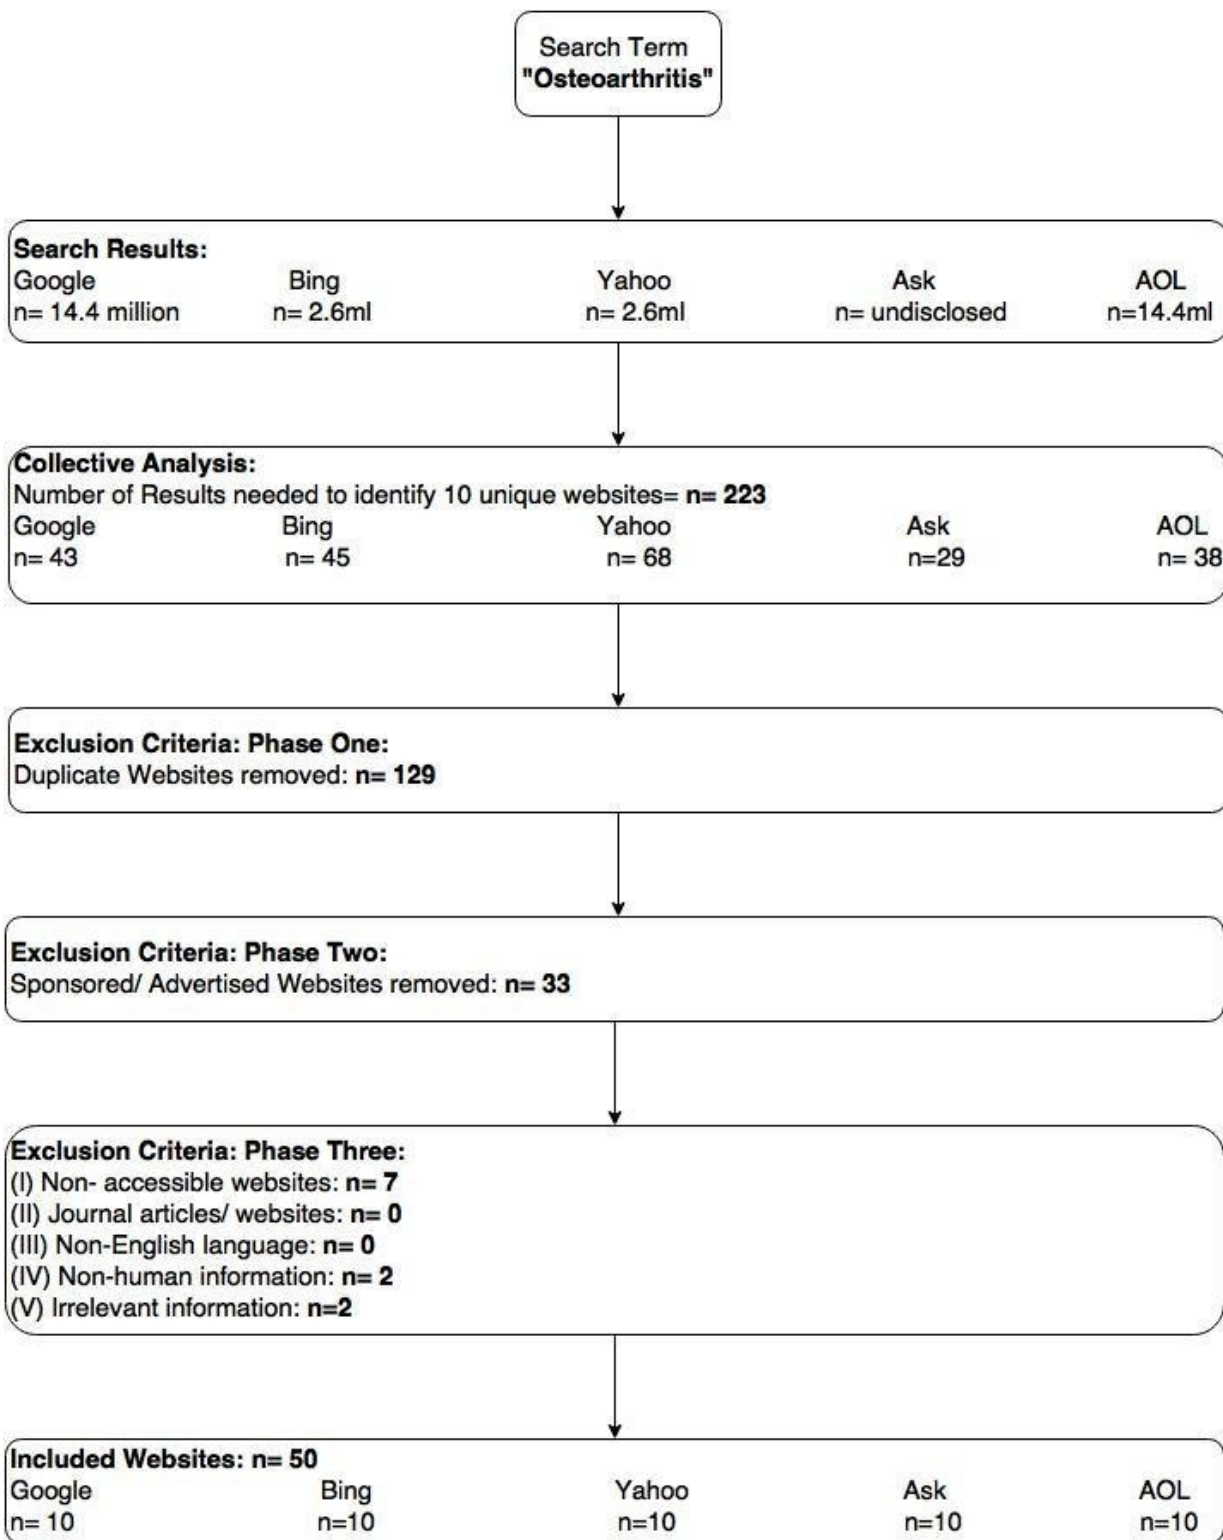

123 generator [24] was used to determine which search engine the website would be
124 allocated to.

125 Once duplicate websites had been removed from the analysis, websites were also
126 excluded if they were sponsored or were advertisements (websites that pay for a
127 higher rank position within the top search results), as these are subject to change
128 with each search and would not be relevant to the studies aims.

129 Following this process websites were additionally excluded if (i) users were denied
130 direct access through password requirements or repeated server unavailability, (ii)
131 they were journal articles or journal websites, (iii) they were not in the English
132 language (iv) they provided information about OA in animals or (v) they contained
133 information irrelevant to the study's aims.

134 This process was completed until 10 unique websites from each search engine were
135 identified. Screenshots were taken of relevant websites and associated URL's were
136 saved within a Microsoft Excel spreadsheet to avoid any potential changes that may
137 have been made to the selected websites during the period of analysis.

138 **Figure 1: Website Search Strategy:**

139

140

141 *Assessment of Website Quality:*

142 To accurately measure and assess the quality of information that is available to a
143 'typical' patient population, websites were appraised using the 'Osteoarthritis Quality
144 Proforma' (OQP) which was developed by the research team (Appendix A). In total,
145 it consisted of 18 criteria, which led to the calculation of three scores:

146 1) *General quality content (criteria 1 to 8)* with a maximum score of 16.

147 2) *Specific OA content (criteria 9 to 18)* with a maximum score of 43.

148 3) *Total score (sum of all criteria)* with a maximum score of 59.

149

150 *General Quality Content:*

151 The general quality criteria were developed based upon several research papers and
152 reviews which have been published on the appraisal of online health and medical
153 information [21, 25, 26]. These were used in conjunction with other widely used
154 quality evaluation tools such as the JAMA benchmarks [27] and the DISCERN
155 instrument [16]. Key criteria that were included within the proforma were disclosure
156 of authorship (and credentials) and funding sources; currency and whether the
157 website was certified by an external organisation such as HoN [15] or the Information
158 Standard [17]. Additional criteria included whether a source of the websites
159 information was provided on the website and whether the site referred the reader
160 onto other useful sources.

161

162 *Specific OA Content:*

163 The criteria used to evaluate content specific to OA were framed around recent NICE
164 guidelines for the care and management of OA [18]. Additionally, International and
165 European guidelines [28, 29] and surrounding literature [30, 31] on the condition

166 were screened and changes made accordingly to ensure that a holistic and
167 comprehensive overview of the disease had been incorporated into the criteria.
168 A total of 10 sections were present within the OA criteria, including information about
169 (i) anatomy and physiology, (ii) risk factors, (iii) symptoms, (iv) diagnosis, (v) holistic
170 approach of the condition, (vi) self-management strategies, (vii) non-pharmalogical
171 treatment, (viii) pharmalogical treatment, (ix) Consideration of surgery and (x) The
172 follow up and review process of the condition.

173

174 Following an initial piloting stage to test the usability and application of the proforma,
175 an Osteoarthritis Quality Proforma (OQP) Guidance Document was produced for
176 assessors to use in conjunction with the OQP. This helped to assist in a more
177 standardised and reproducible process of data collection. Following initial piloting,
178 the OQP demonstrated consistency between assessors, therefore the decision was
179 made for each website to be independently appraised by two researchers and
180 average scores to be calculated. Websites were assessed during a three week
181 period in February 2015, marks were given for the presence of any correct
182 information, and no marks were provided if the information was incorrect.

183 For any websites which had a discrepancy of more than 6 marks between
184 assessors, the researchers met and discussed the websites as a group and any
185 marks which had been incorrectly awarded/ not awarded were discussed and
186 adjusted accordingly. Finalised copies of the OQP and OQP guidance document are
187 available on request to the corresponding author.

188

189 Data were entered into the IBM Statistical Package for the Social Sciences (SPSS)
190 Statistics Version 22 (IBM Corporation 2013). The data was found to be non-

191 normally distributed and therefore non-parametric analysis was used throughout. A
192 Wilcoxon test was used to identify if there were any statistically significant
193 differences between assessors in their use of the OQP tool. Mann-Whitney tests
194 were used to determine if there were statistically significant differences in the overall
195 website quality score in the presence of different website quality indicators (for
196 example between those websites which had or had not received certification from an
197 external organisation).

210 **Results**

211 **Overall Quality Scores:**

212 Of the 50 websites that were assessed the highest score overall was 57 from an
213 available 59 and the lowest was 5. The median total score was 41/59 (69%). The
214 Wilcoxon test highlighted that there was no significant difference between the two
215 assessors' scores ($p=0.192$), supporting the *a priori* decision to use the mean score
216 for analysis. Table 1 gives a complete list of assessed websites and their overall
217 scores. Table 2 reports the analysis of specific quality criteria on overall website
218 quality scores.

219

Oxford					
--------	--	--	--	--	--

221 The research team developed an OQP grading scale. It was based upon the
222 DISCERN grading scale [32], but was modified accordingly to fit our scoring up to
223 59, whereas the DISCERN grading scale grades websites up to a score of 75.
224 Using this scale, with the median of the data being 69% the average quality of the
225 information is categorised as 'good'. Of the 50 assessed websites, seven were
226 categorised as 'Excellent' by the authors' OQP Grading Scale. These websites,
227 which scored 48 or more, were NHSUK, Arthritis Care, BootsWebMD, NICE,
228 OA.About, Healthline and E-medicine health.

229 **General Website Quality:**

230 The general quality scores ranged from 3 to 16 (median 9, 56%) from an available
231 16 marks, indicating that the median was of a 'fair' quality when judged against the
232 authors' OQP Grading Scale. In total 64% (32/50) of the websites scored more than
233 half of the available marks.

234 Of the 50 websites appraised, just under half (24/ 50, 48%) identified a named
235 author or their affiliations. In addition to this, 84% (42/50) of websites appraised
236 provided a date of website creation or when they were last updated; with 64%
237 (32/50) being created/ updated during or after 2014. Sites that had been updated
238 since 2014 had a higher median quality score than those that had not but this was
239 not statistically significant.

240 In total, 36% (18/50) of websites failed to provide a source for their information; with
241 32% (16/50) quoting other sources (such as other websites), and the remaining 32%
242 (16/50) having peer review processes. Websites that had a peer review process had
243 higher median quality scores than those that quoted other sources or none. The

244 difference in quality between those quoting other sources or no sources was not
 245 statistically significant.

246 Of the websites that were assessed, 32% (16/50) had been approved by an external
 247 organisation such as HoN [16] or the Information Standard [17]. Those that had
 248 received external approval had significantly higher median quality scores than those
 249 that had not.

250 The majority of websites (39/50, 78%) referred the reader on to further OA
 251 information, with 58% (29/50) of websites containing links to four or more relevant
 252 sites. Sites that referred on to four or more websites received significantly higher
 253 median quality scores than those that referred to none.

254

255 **Table 2: The influence of specific quality criteria on total quality scores. * =**
 256 statistically significant (Mann Whitney test).

258 **OA Specific Quality Scores:**

259 The OA specific quality scores ranged from 2 to 43 out of a possible 43, with a
 260 median score of 31 (71%), indicating 'good' quality overall using the OQP grading
 261 scale. Of the 50 websites, 72% (36/50) scored over 50% of the available marks.

262 Upon analysing specific criteria many websites scored highly (>half of available
 263 marks) in the reporting of anatomy and physiology (42/50 websites, 84%), risk
 264 factors (42/50 websites, 84%) and symptoms of OA (43/50 websites, 86%). In
 265 addition to this, the diagnosis of OA (37/50 websites, 74%), self-management
 266 strategies (37/50 websites, 74%) and pharmacological management (38/50 websites,
 267 76%) was also well reported throughout. However, scoring at this level was less well
 268 represented in relation to non- pharmacological management (25/50 websites, 50%)
 269 and consideration of surgery (24/50 websites, 48%). Furthermore, the holistic
 270 management of OA (17/50 websites, 34%) and the follow up and review process
 271 (5/50 websites, 10%) were the least well reported sections within the OA criteria.

272 Specific management strategies such as exercise and weight loss were the most
273 frequently documented throughout the assessed websites (84% (42/50) and 80%
274 (40/50) respectively). However, many websites failed to report upon OA effect on
275 sleep (30%, 15/50) and just 26% (13/50) mentioned the possible other medical
276 conditions associated with the disease. In addition to this just 15% (8/50) mentioned
277 the need for regular monitoring of the disease and only 11% (6/50) reported on the
278 importance of regular reviews by a healthcare professional, despite both being
279 highlighted as key recommendations in the NICE [18] guidelines.

280 **Discussion**

281 The purpose of this study was to assess the quality of websites that are available to
282 the public searching for information about OA. Overall, the findings suggest an
283 improvement in the quality of OA websites as previous research had found the
284 quality of OA websites to be poor [4, 6].

285 However, while this study found the overall quality of information to be of a high
286 standard, it is also in accordance with previous research that has found there to be a
287 wide variability in the quality of OA information that is available to users [4, 6]. This
288 helps to highlight that there is a wide inconsistency of information available to users,
289 making it difficult for internet users to consistently access information of a high
290 quality. The reason for this wide discrepancy in quality is multifactorial, with
291 variations occurring in general and OA specific scores.

292 Many websites failed to disclose authorship or affiliations (52%, 26/50) and sources
293 of information (36%, 18/50), while just 32% (16/50) were certified by an external
294 organisation, such as HoN [16]. This highlighted that there were several of the
295 general criteria, which have previously been identified as indicators of quality

296 information [25, 26] which were not well documented by a large proportion of the
297 assessed websites. This is despite the fact that a number of general website
298 indicators were shown to have a significant relationship with the overall quality of a
299 website. Our findings are in accordance with previous research in that quality online
300 information is created more recently, discloses the source of information, has
301 external certification and directs the reader to other useful sites [4, 6].

302 Despite this, the researchers would advise that the results be treated with caution as
303 these relationships were not definitive. There were many websites which scored
304 highly, yet did not disclose these factors, suggesting that these indicators are not
305 pre-requisites to quality information.

306 Over 70% of websites scored over half of the available marks (22 marks or more) on
307 the OA section, indicating that many of the websites published information which
308 was in accordance with the current NICE guidelines [18]. Certain aspects of the
309 NICE guidelines such as anatomy and physiology, risk factors and self-management
310 were well documented throughout. In particular, treatment strategies such as
311 exercise and weight loss were the most frequently cited modalities of the websites
312 that were assessed, highlighting that core modalities recommended in NICE
313 guidelines were present within the appraised websites. Therefore, this information
314 may assist people diagnosed with OA and encourage them towards adhering to
315 healthy lifestyle habits [33].

316 Conversely, the reporting of factors associated with a holistic approach to OA and
317 the follow up and review process were not consistently documented. This is despite
318 the fact that several research papers [34, 35] and guidelines [19] have emphasised
319 the importance of a holistic, patient-centred approach for people affected by OA, with

320 evidence that this approach can help aid function, independence and enhance a
321 person's attitudes towards their disease. It is therefore recommended that healthcare
322 professionals and website developers in the future ensure that sites incorporate a
323 greater range of holistic information for patients. This may include OA effect on sleep
324 and pain management, and a greater emphasis on how it can affect social life and
325 an individual's moods and attitudes.

326 **Limitations:**

327 The results of this study raise some important considerations regarding the quality of
328 OA material available to people online. However, due to several limitations, the
329 results of this study must be considered with caution. Firstly, it should be noted that
330 as the internet is a dynamic entity in which websites move, change or become
331 inaccessible on a continual basis [36], repetition of the current study is likely to result
332 in the identification of different websites. For that reason, while conclusions can be
333 made on the data obtained during February 2015, the results should not be
334 generalised to the quality of OA websites in the future.

335 There are also several limitations with the use of the OQP tool. The creation of the
336 proforma meant that the websites were appraised using a non-standardised and
337 non-validated tool; limiting the validity of the results. Despite this, the present study
338 found there to be good consistency with use of the tool; and so future research
339 would be recommended to assist in validation of the OQP tool.

340 Moreover, the manner in which the OQP appraised websites could also be criticised.
341 While the proforma did not award marks for incorrect information, it did not take into
342 account the level of detail or explanation that individual websites explored for certain
343 criteria and only commented on the presence or otherwise of information. Therefore,

344 to what degree this research accurately assessed the true 'quality' of information is
345 unclear.

346 A further limitation is that the study doesn't reflect the way the general public search
347 for health and medical information. During website appraisal, assessors were using
348 the OQP and guidance document to appraise the information in a systematic and
349 reproducible manner. However, this process of searching for information is
350 somewhat artificial. Previous research has also found that healthcare professionals
351 and consumers evaluate online information in different ways [37]. In light of this,
352 future research may be targeted at facilitating a representative sample of patients or
353 service users to appraise online information as opposed to healthcare practitioners.

354 **Clinical Implications:**

355 Within the internet era, the role of healthcare professionals in guiding patients
356 towards high quality health information has expanded into the digital setting. This
357 study helps to highlight the difficulty healthcare professionals have in recommending
358 an optimal approach to this complex and evolving environment.

359 The wide variability in the quality of OA information available has the potential to not
360 only limit the ability of the patient to become informed and to promote self-
361 management of their condition, but also to directly misinform and mislead healthcare
362 decisions.

363 Within the clinical health setting, more time spent in discussion with patients on
364 aspects such as education about OA may be a beneficial, individualised alternative
365 to online information. For computer literate patients, empowering and educating

366 internet users to find and recognise quality health information for themselves may be
367 a necessary step to help people navigate the myriad of information available to them.

368 Guidelines do not currently exist for the assessment of material online and it may be
369 that formal guidelines can be established or quality assessment criteria delineated
370 and standardised by organisations such as NICE. This would allow consensus of the
371 same method and standard of appraisal for general or specific condition based
372 information, which may be necessary in order to stay ahead of the growing body of
373 inaccurate material on the internet.

374 **Conclusion**

375 The internet has the potential to be a useful tool for educating and empowering
376 healthcare consumers. It can help to facilitate improvements in health status
377 indicators, access to care and enhance communication between patients, families
378 and healthcare professionals [38]. However, if the internet is to assist patients in
379 making informed choices about their health, then digital information needs to be of
380 the highest possible quality.

381 The results of this study show that overall, websites available to a 'typical' population
382 searching for information on OA are of a high standard. However, as previous
383 research has found there is a wide variability in the quality of information available [4,
384 6]. Internet users are therefore at risk of accessing material that is unsubstantiated
385 and unreliable, which can negatively impact upon patient decision making.

386 It is therefore of the utmost importance that healthcare professionals become
387 proactive in evaluating existing information online to help patients locate reliable and
388 accurate information. In addition to this, in the future practitioners should become

389 actively involved with website developers in establishing high quality, evidence
390 based websites.

391 *Funding:* This study has not been funded by any third parties to influence the
392 outcome and findings in anyway. Any costs incurred during the research process
393 have been the sole responsibility of the researcher team.

394 *Conflict of interest:* None
